- Distributed memory systems are very common
- Rate of computation vs rate of data movement
- Focus: Avoid, Hide, and Minimize communication costs

# Task Graphs and Runtime Systems

- Application can be expressed as a task graph
- Vertices represent tasks
- Edges represent dependencies among tasks

## Task Based Runtime Systems

- QUARK, PaRSEC, StarPU, StarSs, Legion
- May only see a set of ready (independent) tasks
- A memory node may require data from other memory nodes
- Order of data transfers such that communication-computation overlap is maximized

# Task Graphs and Runtime Systems

- Application can be expressed as a task graph
- Vertices represent tasks
- Edges represent dependencies among tasks

## Task Based Runtime Systems

- QUARK, PaRSEC, StarPU, StarSs, Legion
- May only see a set of ready (independent) tasks
- A memory node may require data from other memory nodes
- Order of data transfers **between two memory nodes** such that communication-computation overlap is maximized

# Table of Contents

## 1. Introduction

## 2. Problem Definition

- Unlimited Memory Capacity
- Limited Memory Capacity

## 3. Classes of Heuristics

- Static Order Based Strategies
- Dynamic Selection Based Strategies
- Static Order with Dynamic Corrections Based Strategies

## 4. Workloads & Hardware Configurations

## 5. Conclusion and Ongoing Work

# Problem Definition

- Communication and computation times are known
  - ▶ Based on number of computations and hardware details
  - ▶ Obtained from previous executions (or iterations)

## Problem *DT*

- A set of tasks  $ST = \{T_1, \dots, T_n\}$  is scheduled on a processing unit  $P$  with memory unit  $M$  of capacity  $C$
- Input data for tasks of  $ST$  reside on another memory unit
- Tasks do not produce output data
- Tasks do not require intermediate memory
- A task uses an amount of memory in  $M$  from the start of its communication to the end of its computation

Given  $L$ , is there a feasible schedule  $S$  for  $ST$  such that makespan of  $S$ ,  $\mu(S) \leq L$ ?

## Machine Flowshop Problem

- $n$  machines and  $m$  tasks
- Each task contains exactly  $n$  operations
- $i$ -th operation of a task must be processed on the  $i$ -th machine
- Each machine can perform at-max one operation at a time
- $i$ -th operation of a task starts after the completion of  $(i - 1)$ -th operation

The problem is to obtain the arrangement that achieves shortest possible makespan.

- Johnson provided an optimal algorithm for 2-machine flow shop problem
- Our problem  $DT$  adds one extra dimension (memory capacity) to 2-machine flowshop problem

## 1. Introduction

## 2. Problem Definition

- Unlimited Memory Capacity
- Limited Memory Capacity

## 5. Conclusion and Ongoing Work

# Unlimited Memory Capacity

## Johnson's Algorithm

- 1: Divide ready tasks in two sets  $S_1$  and  $S_2$ . If computation time of a task  $T$  is not less than its communication time, then  $T$  is in  $S_1$  otherwise in  $S_2$ .
- 2: Sort  $S_1$  in queue  $Q$  by non-decreasing communication times
- 3: Sort  $S_2$  in queue  $Q'$  by non-increasing computation times
- 4: Append  $Q'$  to  $Q$
- 5:  $\tau_{\text{COMM}} \leftarrow 0$                       {Available time of communication resource}
- 6:  $\tau_{\text{COMP}} \leftarrow 0$                       {Available time of computation resource}
- 7: **while**  $Q \neq \emptyset$  **do**
- 8:     Remove a task  $T$  from beginning of  $Q$  for processing
- 9:      $S_{\text{COMM}}(T) \leftarrow \tau_{\text{COMM}}$
- 10:     $S_{\text{COMP}}(T) \leftarrow \max(S_{\text{COMM}}(T) + \text{COMM}_T, \tau_{\text{COMP}})$
- 11:     $\tau_{\text{COMM}} \leftarrow S_{\text{COMM}}(T) + \text{COMM}_T$
- 12:     $\tau_{\text{COMP}} \leftarrow S_{\text{COMP}}(T) + \text{COMP}_T$
- 13: **end while**

- *OMIM* denotes the makespan of this algorithm

# Approach for the Optimality Proof

Original Schedule

Swapped Schedule

## 1. Introduction

## 2. Problem Definition

- Unlimited Memory Capacity
- Limited Memory Capacity

## 3. Classes of Heuristics

- Static Order Based Strategies
- Dynamic Selection Based Strategies
- Static Order with Dynamic Corrections Based Strategies

## 4. Workloads & Hardware Configurations

## 5. Conclusion and Ongoing Work

- Memory is required only to store input data (from the definition of our problem)
- As communication time  $\propto$  amount of communication, for each task:
  - ▶ Communication time = Amount of communication (for simplification)
  - ▶ Communication time = Amount of input data

## Reduction Problem

**Three Partition Problem (3PAR):** Given a set of  $3m$  integers  $A = \{a_1, \dots, a_{3m}\}$ , is there a partition of  $A$  into  $m$  triplets  $TR_i = \{a_{i_1}, a_{i_2}, a_{i_3}\}$ , such that  $\forall i, a_{i_1} + a_{i_2} + a_{i_3} = b$ , where  $b = (1/m) \sum a_i$ ?

## Definition of tasks in the reduction from 3PAR

$$x = \max\{a_i : 1 \leq i \leq 3m\}$$

Task	Communication time	Computation time
$K_0$	0	3
$K_1, \dots, K_{m-1}$	$b' = b + 6x$	3
$K_m$	$b' = b + 6x$	0
$1 \leq i \leq 3m, A_i$	1	$a'_i = a_i + 2x$

Total memory capacity:  $C = b' + 3$

Target makespan:  $L = m(b' + 3)$

# Pattern of Feasible Schedule

- Problem  $DT$  is NP-Complete.
- Our proof is inspired from work by Papadimitriou et al. (on 2-machine flowshop with limited buffer problem)

# Order of Processing on Communication and Computation Resources in Optimal Schedules

Task	Memory Req	Comm Time	Comp Time
A	0	0	5
B	4	4	3
C	1	1	6
D	3	3	7
E	6	6	0.5
F	7	7	0.5

Memory Capacity = 10

## Common ordering on both resources

## Different ordering on both resources

# Table of Contents

## 1. Introduction

## 2. Problem Definition

- Unlimited Memory Capacity
- Limited Memory Capacity

## 3. Classes of Heuristics

- Static Order Based Strategies
- Dynamic Selection Based Strategies
- Static Order with Dynamic Corrections Based Strategies

## 4. Workloads & Hardware Configurations

## 5. Conclusion and Ongoing Work

- Static order based strategies
- Dynamic selection based strategies
- Static order with dynamic correction based strategies

We consider common order on both resources for all of our heuristics.

# Static Order Based Strategies

- *order of optimal strategy infinite memory (OOSIM)*
- *increasing order of communication strategy (IOCMS)*
- *decreasing order of computation strategy (DOCPS)*
- *increasing order of communication plus computation strategy (IOCCS)*
- *decreasing order of communication plus computation strategy (DOCCS)*

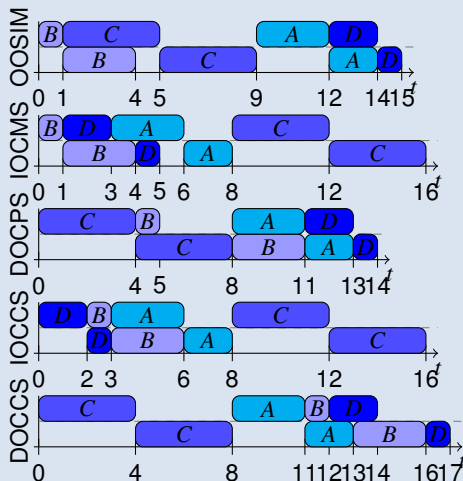

# Static Order Based Strategies

Task	Memory Req	Comm Time	Comp Time
A	3	3	2
B	1	1	3
C	4	4	4
D	2	2	1

## Unlimited Memory Capacity

## Memory Capacity: 6

- *largest communication task respects memory restriction (LCMR)*
- *smallest communication task respects memory restriction (SCMR)*
- *maximum accelerated task respects memory restriction (MAMR)*

# Dynamic Selection Based Strategies

Task	Memory Req	Comm Time	Comp Time
A	3	3	2
B	1	1	6
C	4	4	6
D	5	5	1

Memory Capacity = 6

# Static Order with Dynamic Corrections Based Strategies

- *optimal order infinite memory largest communication task respects memory restriction (OOLCMR)*
- *optimal order infinite memory smallest communication task respects memory restriction (OOSCMR)*
- *optimal order infinite memory maximum accelerated task respects memory restriction (OOMAMR)*

# Static Order with Dynamic Corrections Based Strategies

Task	Memory Req	Comm Time	Comp Time
A	4	4	1
B	2	2	6
C	8	8	8
D	5	5	4
E	3	3	2

OMIM order = BCDEA

Memory Capacity=9

# Favorable Situations for Heuristics

Heuristic	Favorable Situation
<i>OOSIM</i>	Memory capacity is not a restriction (Optimal)
<i>IOCMS</i>	Memory capacity is not a restriction and tasks are compute intensive (Optimal)
<i>DOCPS</i>	Memory capacity is not a restriction and tasks are communication intensive (Optimal)
<i>IOCCS</i>	Moderate memory capacity and most tasks are highly compute intensive
<i>DOCCS</i>	Moderate memory capacity and most tasks are highly communication intensive
<i>LCMR</i>	Limited memory capacity and significant percentage of tasks with large communication times are compute intensive
<i>SCMR</i>	Limited memory capacity and significant percentage of tasks with small communication times are compute intensive
<i>MAMR</i>	Limited memory capacity and significant percentage of all types of tasks
<i>OOLCMR</i>	Moderate memory capacity and significant percentage of slightly communication intensive tasks have large communication times
<i>OOSCMR</i>	Moderate memory capacity and significant percentage of slightly communication intensive tasks have small communication times
<i>OOMAMR</i>	Moderate memory capacity and significant percentage of all types of tasks

## *Gilmore-Gomory (GG)*

- A classical algorithm for 2-machine no-wait flowshop problem
- Problem is represented by a graph
- An optimal sequence of vertices is obtained
- Does not take memory constraints into account

## *Bin Packing (BP)*

- First-Fit algorithm for the bin packing problem
- Tasks added to the first bin in which they fit
- If no bin is found then a new bin is created
- Sequence is made of all tasks from consecutive bins

# Table of Contents

## 1. Introduction

## 2. Problem Definition

- Unlimited Memory Capacity
- Limited Memory Capacity

## 3. Classes of Heuristics

- Static Order Based Strategies
- Dynamic Selection Based Strategies
- Static Order with Dynamic Corrections Based Strategies

## 4. Workloads & Hardware Configurations

## 5. Conclusion and Ongoing Work

## Molecular Chemistry Kernels

- Hartree–Fock (HF) with SiOSi molecules and Coupled Cluster Singles Doubles (CCSD) with Uracil molecules
- Tensor operations: transpose and contraction

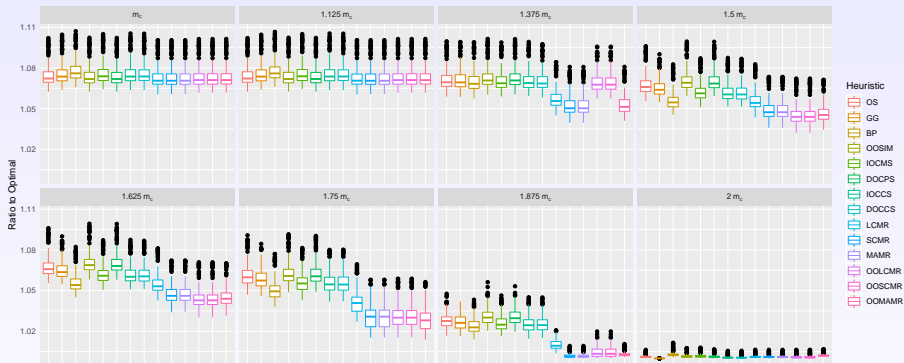

# Configuration Parameters to Obtain Traces

- 10 nodes of Cascade machine
- Each node contains 16 Intel Xeon E5-2670 cores
- Double precision version of HF and CCSD of NWChem
- NWChem takes advantages of Global Arrays (GA)
- 150 processes for each application, 300-800 tasks for each process

## Simulation Parameters

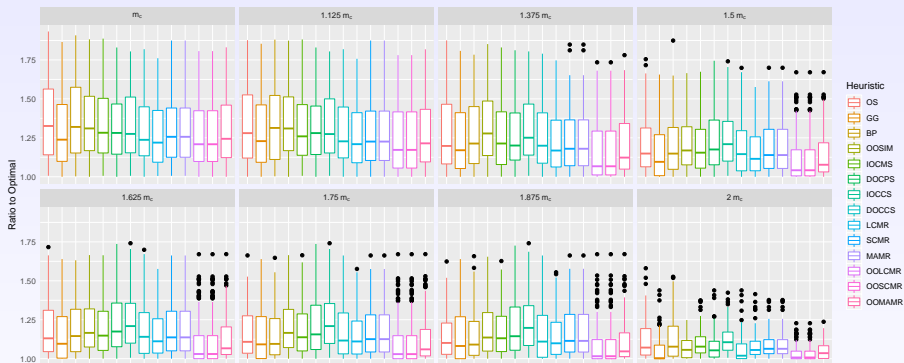

- $m_c$ : minimum memory capacity requirement to execute all tasks of an application
- Evaluation criteria for a heuristic  $H$ ,  $r(H) = \frac{\text{makespan of } H}{OMIM}$  (lower values are better)
- All data transfers between the local memory of each process and the GA memory take the same route

# HF Performance with $m_c = 176KB$ .

- Dynamic strategies are best suited for limited memory capacities
- Static order with dynamic correction variants outperform others for moderate memory capacities

# CCSD Performance with $m_c = 1.8GB$

- Highly heterogeneous tasks
- Static order with dynamic correction variants outperform others in most cases

# Best Variants of All Categories

## HF Performance

# Best Variants of All Categories

## CCSD Performance

- Impact of congestion on communication/computation times
- Output data of a task
- Multiple routes between two memory nodes
- Communications from multiple memory nodes can happen at the same time

# Table of Contents

## 1. Introduction

## 2. Problem Definition

- Unlimited Memory Capacity
- Limited Memory Capacity

## 3. Classes of Heuristics

- Static Order Based Strategies
- Dynamic Selection Based Strategies
- Static Order with Dynamic Corrections Based Strategies

## 4. Workloads & Hardware Configurations

## 5. Conclusion and Ongoing Work

## Conclusion:

- Problem of determining the optimal order of data transfers is NP-complete
- Our heuristics achieve significant overlap for HF and CCSD applications

## Ongoing work:

- Evaluation of our heuristics in the context of accelerators
- Implementation of the proposed heuristics
- Automatic selection of the best heuristic

Thank  
You!
